QUERY OPTIMIZATION

For a given query, find a **correct** execution plan that has the lowest "cost".

This is the part of a DBMS that is the hardest to implement well (proven to be NP-Complete).

 \rightarrow If you are good at this, you will get paid \$\$\$.

No optimizer truly produces the "optimal" plan

- → Use estimation techniques to guess real plan cost.
- \rightarrow Use heuristics to limit the search space.

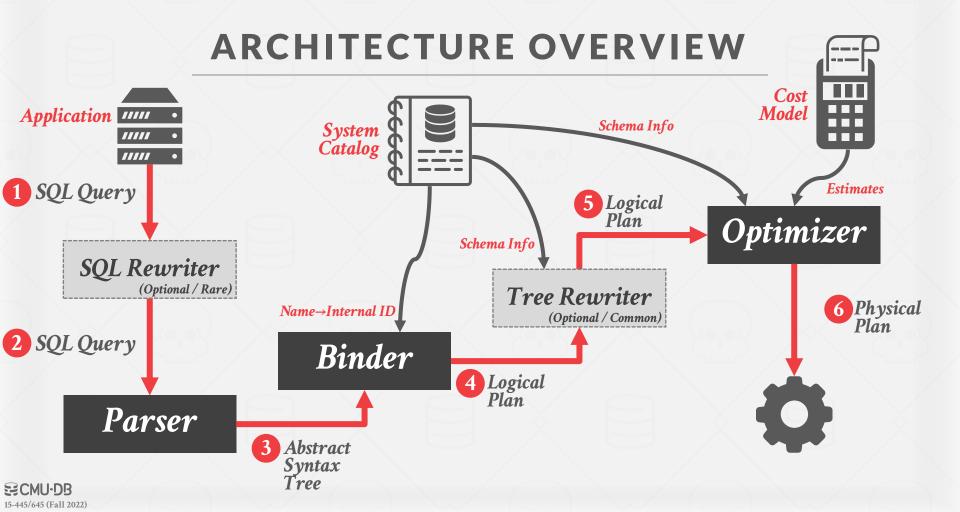

LOGICAL VS. PHYSICAL PLANS

The optimizer generates a mapping of a <u>logical</u> algebra expression to the optimal equivalent physical algebra expression.

Physical operators define a specific execution strategy using an access path.

- → They can depend on the physical format of the data that they process (i.e., sorting, compression).
- → Not always a 1:1 mapping from logical to physical.

QUERY OPTIMIZATION

Heuristics / Rules

- → Rewrite the query to remove stupid / inefficient things.
- → These techniques may need to examine catalog, but they do <u>not</u> need to examine data.

Cost-based Search

- \rightarrow Use a model to estimate the cost of executing a plan.
- → Enumerate multiple equivalent plans for a query and pick the one with the lowest cost.

TODAY'S AGENDA

Heuristic/Ruled-based Optimization
Query Cost Models
Cost-based Optimization

LOGICAL PLAN OPTIMIZATION

Transform a logical plan into an equivalent logical plan using pattern matching rules.

The goal is to increase the likelihood of enumerating the optimal plan in the search.

Cannot compare plans because there is no cost model but can "direct" a transformation to a preferred side.

LOGICAL QUERY OPTIMIZATION

Split Conjunctive Predicates

Predicate Pushdown

Replace Cartesian Products with Joins

Projection Pushdown

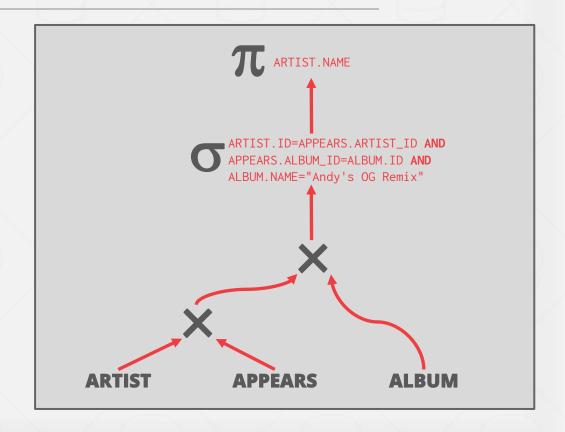

Source: Thomas Neumann

SPLIT CONJUNCTIVE PREDICATES

SELECT ARTIST.NAME
FROM ARTIST, APPEARS, ALBUM
WHERE ARTIST.ID=APPEARS.ARTIST_ID
AND APPEARS.ALBUM_ID=ALBUM.ID
AND ALBUM.NAME="Andy's OG Remix"

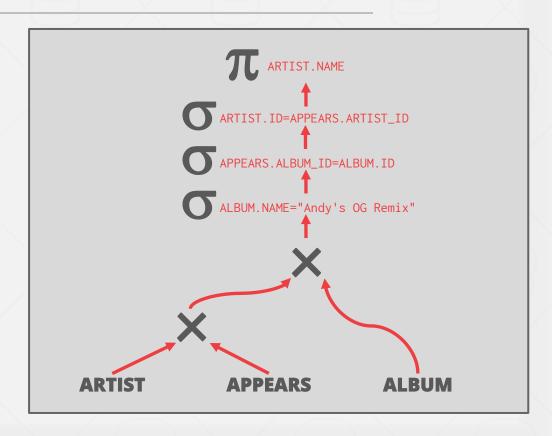

Decompose predicates into their simplest forms to make it easier for the optimizer to move them around.

PREDICATE PUSHDOWN

SELECT ARTIST.NAME
FROM ARTIST, APPEARS, ALBUM
WHERE ARTIST.ID=APPEARS.ARTIST_ID
AND APPEARS.ALBUM_ID=ALBUM.ID
AND ALBUM.NAME="Andy's OG Remix"

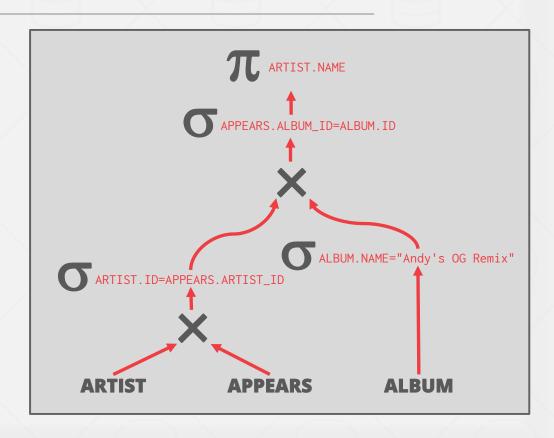

Move the predicate to the lowest applicable point in the plan.

REPLACE CARTESIAN PRODUCTS

SELECT ARTIST.NAME
FROM ARTIST, APPEARS, ALBUM
WHERE ARTIST.ID=APPEARS.ARTIST_ID
AND APPEARS.ALBUM_ID=ALBUM.ID
AND ALBUM.NAME="Andy's OG Remix"

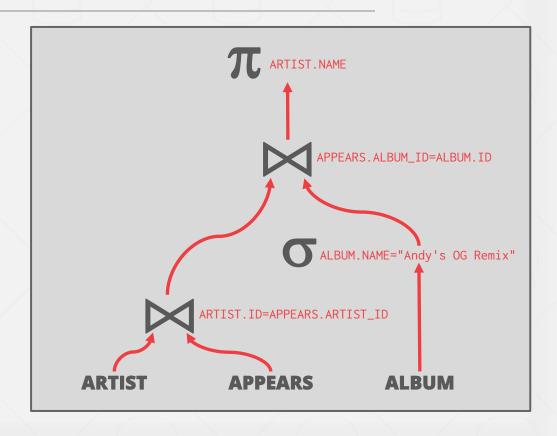

Replace all Cartesian Products with inner joins using the join predicates.

PROJECTION PUSHDOWN

SELECT ARTIST.NAME
FROM ARTIST, APPEARS, ALBUM
WHERE ARTIST.ID=APPEARS.ARTIST_ID
AND APPEARS.ALBUM_ID=ALBUM.ID
AND ALBUM.NAME="Andy's OG Remix"

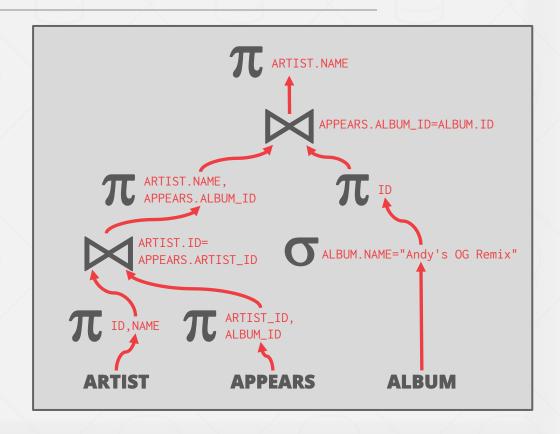

Eliminate redundant attributes before pipeline breakers to reduce materialization cost.

PROJECTION PUSHDOWN

SELECT ARTIST.NAME
FROM ARTIST, APPEARS, ALBUM
WHERE ARTIST.ID=APPEARS.ARTIST_ID
AND APPEARS.ALBUM_ID=ALBUM.ID
AND ALBUM.NAME="Andy's OG Remix"

Eliminate redundant attributes before pipeline breakers to reduce materialization cost.

NESTED SUB-QUERIES

The DBMS treats nested sub-queries in the where clause as functions that take parameters and return a single value or set of values.

Two Approaches:

- → Rewrite to de-correlate and/or flatten them
- → Decompose nested query and store result to temporary table

NESTED SUB-QUERIES: REWRITE

```
SELECT name FROM sailors AS S
WHERE EXISTS (
    SELECT * FROM reserves AS R
    WHERE S.sid = R.sid
    AND R.day = '2022-10-25'
)
```

```
SELECT name
FROM sailors AS S, reserves AS R
WHERE S.sid = R.sid
AND R.day = '2022-10-25'
```

For harder queries, the optimizer breaks up queries into blocks and then concentrates on one block at a time.

Sub-queries are written to a temporary table that are discarded after the query finishes.

```
|SELECT S.sid, MIN(R.day)
  FROM sailors S, reserves R, boats B
 WHERE S.sid = R.sid
   AND R.bid = B.bid
   AND B.color = 'red'
   AND S.rating = (SELECT MAX(S2.rating)
                     FROM sailors S2)
 GROUP BY S.sid
HAVING COUNT(*) > 1
                      Nested Block
```

```
SELECT MAX(rating) FROM sailors
SELECT S.sid, MIN(R.day)
  FROM sailors S, reserves R, boats B
 WHERE S.sid = R.sid
   AND R.bid = B.bid
   AND B.color = 'red'
   AND S.rating = ### ←
 GROUP BY S.sid
HAVING COUNT(*) > 1
```

```
SELECT MAX(rating) FROM sailors
SELECT S.sid, MIN(R.day)
  FROM sailors S, reserves R, boats B
 WHERE S.sid = R.sid
   AND R.bid = B.bid
   AND B.color = 'red'
   AND S.rating = ### ←
 GROUP BY S.sid
HAVING COUNT(*) > 1
```

Outer Block

An optimizer transforms a query's expressions (e.g., WHERE/ON clause predicates) into the minimal set of expressions.

Implemented using if/then/else clauses or a pattern-matching rule engine.

- \rightarrow Search for expressions that match a pattern.
- \rightarrow When a match is found, rewrite the expression.
- \rightarrow Halt if there are no more rules that match.

Impossible / Unnecessary Predicates

SELECT * FROM A WHERE 1 = 0

Impossible / Unnecessary Predicates

SELECT * **FROM** A **WHERE** false;

SELECT * FROM A WHERE NOW() IS NULL;

Impossible / Unnecessary Predicates

```
SELECT * FROM A WHERE false;
```

```
SELECT * FROM A WHERE false;
```

```
SELECT * FROM A WHERE RANDOM() IS NULL;
```

Impossible / Unnecessary Predicates

```
SELECT * FROM A WHERE false;

SELECT * FROM A WHERE false;

SELECT * FROM A WHERE RANDOM() IS NULL;
```

Merging Predicates

```
SELECT * FROM A
WHERE val BETWEEN 1 AND 100
OR val BETWEEN 50 AND 150;
```

Impossible / Unnecessary Predicates

```
SELECT * FROM A WHERE false;
```

SELECT * **FROM** A **WHERE** false;

SELECT * FROM A WHERE RANDOM() IS NULL;

Merging Predicates

```
SELECT * FROM A
WHERE val BETWEEN 1 AND 150;
```

QUERY OPTIMIZATION

Heuristics / Rules

- → Rewrite the query to remove stupid / inefficient things.
- → These techniques may need to examine catalog, but they do <u>not</u> need to examine data.

Cost-based Search

- \rightarrow Use a model to estimate the cost of executing a plan.
- → Enumerate multiple equivalent plans for a query and pick the one with the lowest cost.

COST ESTIMATION

The DBMS uses a cost model to predict the behavior of a query plan given a database state.

→ This is an <u>internal</u> cost that allows the DBMS to compare one plan with another.

It is too expensive to run every possible plan to determine this information, so the DBMS need a way to derive this information.

COST MODEL COMPONENTS

Choice #1: Physical Costs

- → Predict CPU cycles, I/O, cache misses, RAM consumption, network messages...
- → Depends heavily on hardware.

Choice #2: Logical Costs

- \rightarrow Estimate output size per operator.
- → Independent of the operator algorithm.
- → Need estimations for operator result sizes.

Choice #3: Algorithmic Costs

→ Complexity of the operator algorithm implementation.

POSTGRES COST MODEL

Uses a combination of CPU and I/O costs that are weighted by "magic" constant factors.

Default settings are obviously for a disk-resident database without a lot of memory:

- → Processing a tuple in memory is **400x** faster than reading a tuple from disk.
- \rightarrow Sequential I/O is **4x** faster than random I/O.

19.7.2. Planner Cost Constants

The *cost* variables described in this section are measured on an arbitrary scale. Only their relative values matter, hence scaling them all up or down by the same factor will result in no change in the planner's choices. By default, these cost variables are based on the cost of sequential page fetches; that is, seq_page_cost is conventionally set to 1.0 and the other cost variables are set with reference to that. But you can use a different scale if you prefer, such as actual execution times in milliseconds on a particular machine.

Note: Unfortunately, there is no well-defined method for determining ideal values for the cost variables. They are best treated as averages over the entire mix of queries that a particular installation will receive. This means that changing them on the basis of just a few experiments is very risky.

seq_page_cost (floating point)

Sets the planner's estimate of the cost of a disk page fetch that is part of a series of sequential fetches. The default is 1.0. This value can be overridden for tables and indexes in a particular tablespace by setting the tablespace parameter of the same name (see ALTER TABLESPACE).

random_page_cost (floating point)

STATISTICS

The DBMS stores internal statistics about tables, attributes, and indexes in its internal catalog. Different systems update them at different times.

Manual invocations:

- → Postgres/SQLite: **ANALYZE**
- → Oracle/MySQL: **ANALYZE TABLE**
- → SQL Server: **UPDATE STATISTICS**
- → DB2: RUNSTATS

SELECTION CARDINALITY

Formula depends on type of predicate:

- → Equality
- → Range
- → Negation
- → Conjunction
- → Disjunction

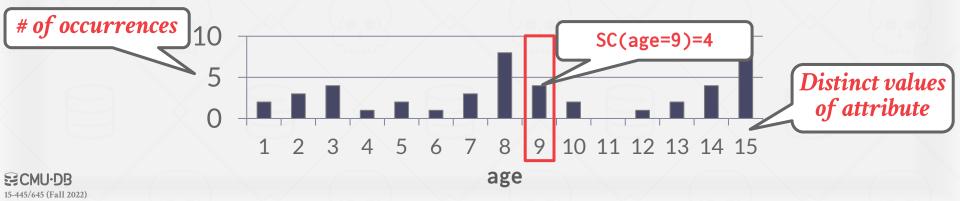

SELECTION CARDINALITY

The **selectivity** (**sel**) of a predicate **P** is the fraction of tuples that qualify.

Equality Predicate: A=constant

- → sel(A=constant) = #occurences/|R|
- \rightarrow Example: sel(age=9) = 4/45

SELECT * FROM people WHERE age = 9

SELECTION CARDINALITY

Assumption #1: Uniform Data

→ The distribution of values (except for the heavy hitters) is the same.

Assumption #2: Independent Predicates

→ The predicates on attributes are independent

Assumption #3: Inclusion Principle

→ The domain of join keys overlap such that each key in the inner relation will also exist in the outer table.

CORRELATED ATTRIBUTES

Consider a database of automobiles:

 \rightarrow # of Makes = 10, # of Models = 100

And the following query:

With the independence and uniformity assumptions, the selectivity is:

$$\rightarrow 1/10 \times 1/100 = 0.001$$

But since only Honda makes Accords the real selectivity is 1/100 = 0.01

STATISTICS

Choice #1: Histograms

→ Maintain an occurrence count per value (or range of values) in a column.

Choice #2: Sketches

→ Probabilistic data structure that gives an approximate count for a given value.

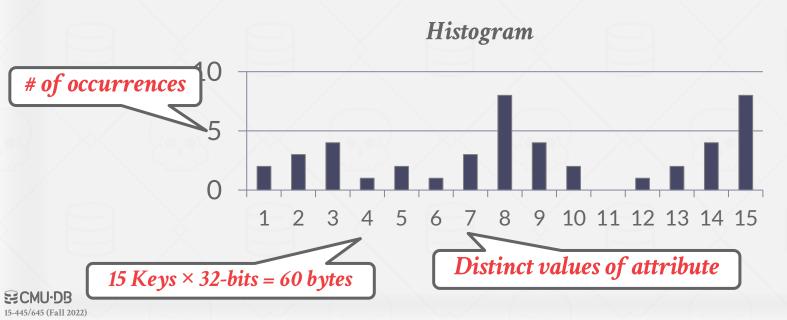

Choice #3: Sampling

→ DBMS maintains a small subset of each table that it then uses to evaluate expressions to compute selectivity.

HISTOGRAMS

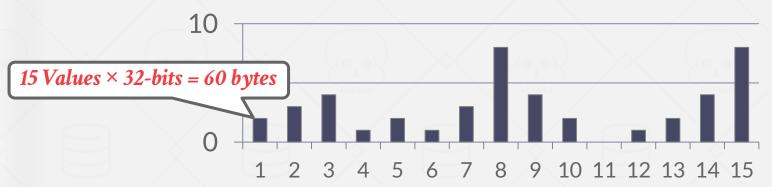

Our formulas are nice, but we assume that data values are uniformly distributed.

EQUI-WIDTH HISTOGRAM

Maintain counts for a group of values instead of each unique key. All buckets have the same width (i.e., same # of value).

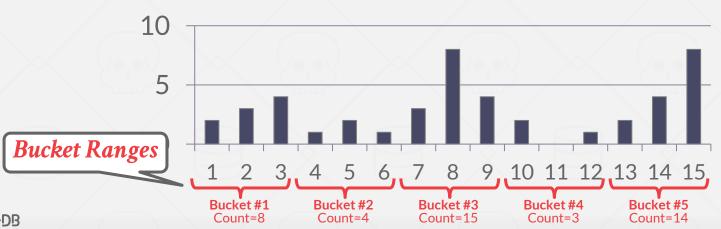

EQUI-WIDTH HISTOGRAM

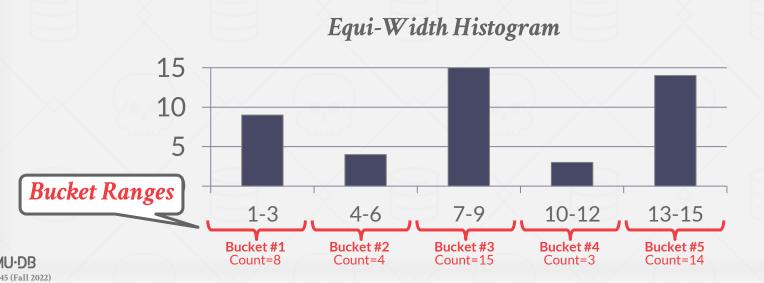

Maintain counts for a group of values instead of each unique key. All buckets have the same width (i.e., same # of value).

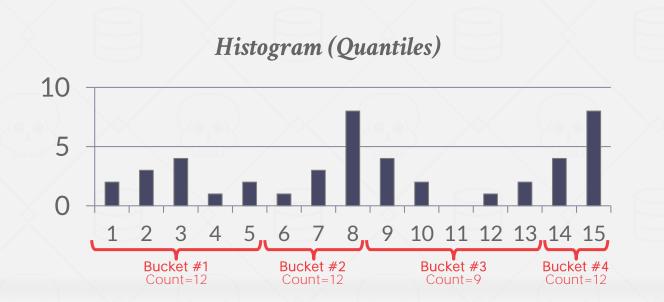

EQUI-WIDTH HISTOGRAM

Maintain counts for a group of values instead of each unique key. All buckets have the same width (i.e., same # of value).

EQUI-DEPTH HISTOGRAMS

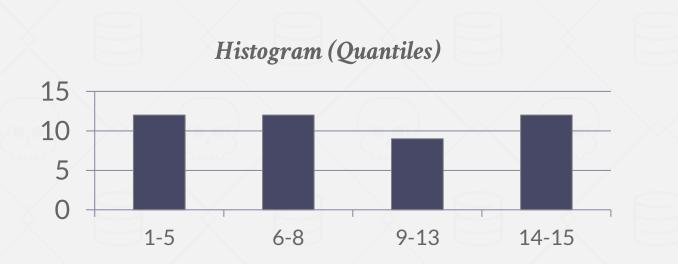

Vary the width of buckets so that the total number of occurrences for each bucket is roughly the same.

EQUI-DEPTH HISTOGRAMS

Vary the width of buckets so that the total number of occurrences for each bucket is roughly the same.

SKETCHES

Probabilistic data structures that generate approximate statistics about a data set.

Cost-model can replace histograms with sketches to improve its selectivity estimate accuracy.

Most common examples:

- → Count-Min Sketch (1988): Approximate frequency count of elements in a set.
- → <u>HyperLogLog</u> (2007): Approximate the number of distinct elements in a set.

SAMPLING

Modern DBMSs also collect samples from tables to estimate selectivities.

Update samples when the underlying tables changes significantly.

Table Sample

 1001
 Obama
 61
 Rested

 1003
 Tupac
 25
 Dead

 1005
 Andy
 41
 Illin

FROM people
WHERE age > 50

id	name	age	status
1001	Obama	61	Rested
1002	Kanye	45	Weird
1003	Tupac	25	Dead
1004	Bieber	28	Crunk
1005	Andy	41	Illin
1006	TigerKing	59	Jailed

sel(age>50) = 1/3

OBSERVATION

Now that we can (roughly) estimate the selectivity of predicates, and subsequently the cost of query plans, what can we do with them?

QUERY OPTIMIZATION

After performing rule-based rewriting, the DBMS will enumerate different plans for the query and estimate their costs.

- \rightarrow Single relation.
- \rightarrow Multiple relations.
- → Nested sub-queries.

It chooses the best plan it has seen for the query after exhausting all plans or some timeout.

SINGLE-RELATION QUERY PLANNING

Pick the best access method.

- → Sequential Scan
- → Binary Search (clustered indexes)
- → Index Scan

Predicate evaluation ordering.

Simple heuristics are often good enough for this.

OLTP queries are especially easy...

OLTP QUERY PLANNING

Query planning for OLTP queries is easy because they are **sargable** (**S**earch **Arg**ument **Able**).

- \rightarrow It is usually just picking the best index.
- → Joins are almost always on foreign key relationships with a small cardinality.
- \rightarrow Can be implemented with simple heuristics.

```
CREATE TABLE people (
   id INT PRIMARY KEY,
   val INT NOT NULL,
   i:
   );
SELECT * FROM people
WHERE id = 123;
```

MULTI-RELATION QUERY PLANNING

Choice #1: Bottom-up Optimization

→ Start with nothing and then build up the plan to get to the outcome that you want.

Choice #2: Top-down Optimization

→ Start with the outcome that you want, and then work down the tree to find the optimal plan that gets you to that goal.

BOTTOM-UP OPTIMIZATION

Use static rules to perform initial optimization. Then use dynamic programming to determine the best join order for tables using a divide-and-conquer search method

Examples: IBM System R, DB2, MySQL, Postgres, most open-source DBMSs.

Break query up into blocks and generate the logical operators for each block.

For each logical operator, generate a set of physical operators that implement it.

→ All combinations of join algorithms and access paths

Selinger

Then iteratively construct a "left-deep" join tree that minimizes the estimated amount of work to execute the plan.

SELECT ARTIST.NAME

FROM ARTIST, APPEARS, ALBUM

WHERE ARTIST.ID=APPEARS.ARTIST_ID

AND APPEARS.ALBUM_ID=ALBUM.ID

AND ALBUM.NAME="Andy's OG Remix"

ORDER BY ARTIST.ID

Step #1: Choose the best access paths to each table

Step #2: Enumerate all possible join orderings for tables

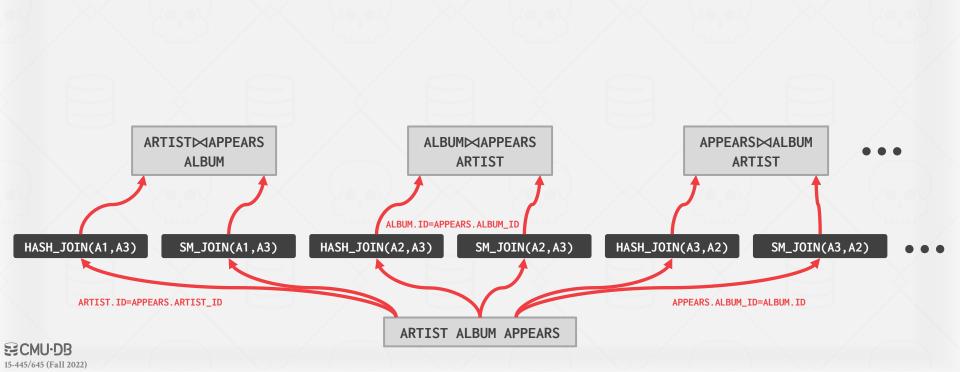

Step #3: Determine the join ordering with the lowest cost

ARTIST: Sequential Scan

APPEARS: Sequential Scan

ALBUM: Index Look-up on NAME

ARTIST ⋈ APPEARS ⋈ ALBUM

ARTIST ⋈ APPEARS ⋈ ALBUM

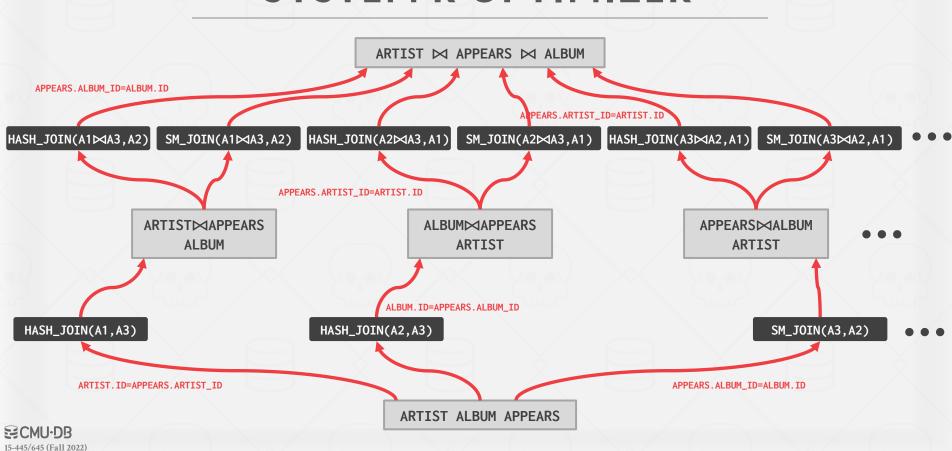

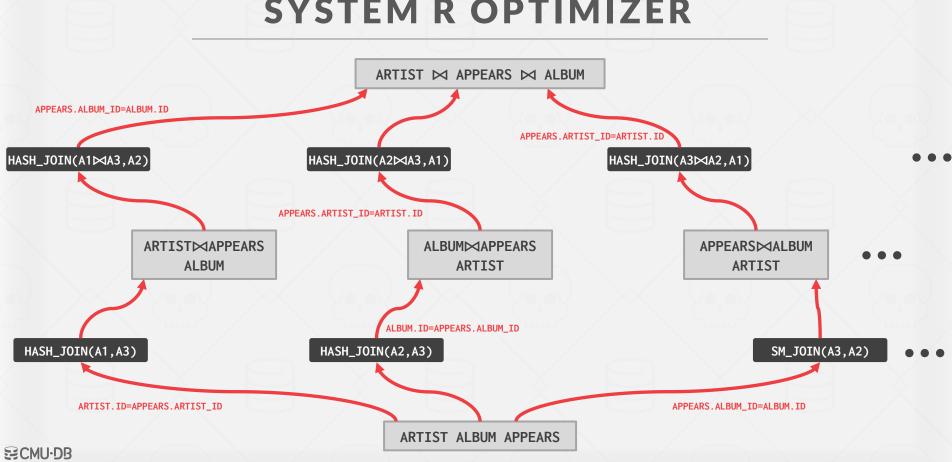

15-445/645 (Fall 2022)

APPEARS ⋈ ALBUM ARTIST

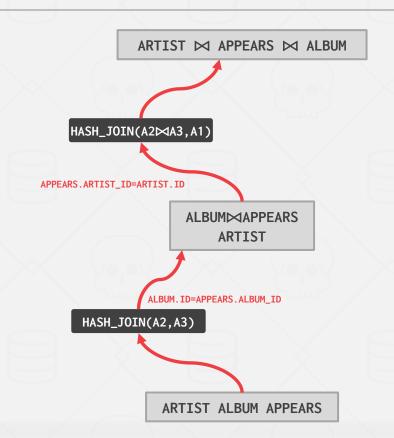

SM_JOIN(A3,A2)

APPEARS.ALBUM_ID=ALBUM.ID

15-445/645 (Fall 2022)

Start with a logical plan of what we want the query to be. Perform a branch-and-bound search to traverse the plan tree by converting logical operators into physical operators.

- → Keep track of global best plan during search.
- → Treat physical properties of data as first-class entities during planning.

Graefe

Example: MSSQL, Greenplum, CockroachDB

Invoke rules to create new nodes and traverse tree.

- \rightarrow Logical \rightarrow Logical:
 - JOIN(A,B) to JOIN(B,A)
- → Logical→Physical:

JOIN(A,B) to HASH_JOIN(A,B)

ARTIST ⋈ APPEARS ⋈ ALBUM ORDER-BY(ARTIST.ID)

ARTIST⋈APPEARS

ALBUMAPPEARS

ARTIST⋈ALBUM

ARTIST

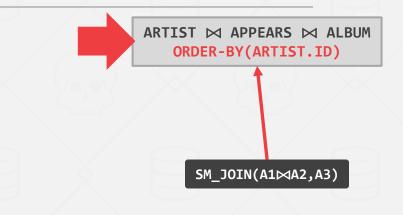

ALBUM

APPEARS

Invoke rules to create new nodes and traverse tree.

- → Logical→Logical: JOIN(A,B) to JOIN(B,A)
- \rightarrow Logical \rightarrow Physical:

JOIN(A,B) to HASH_JOIN(A,B)

ALBUMAPPEARS

ARTISTMALBUM

ARTIST

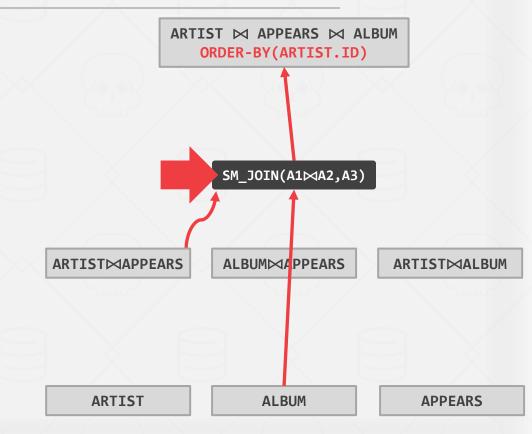

ALBUM

APPEARS

Invoke rules to create new nodes and traverse tree.

- → Logical→Logical:
 - JOIN(A,B) to JOIN(B,A)
- \rightarrow Logical \rightarrow Physical:

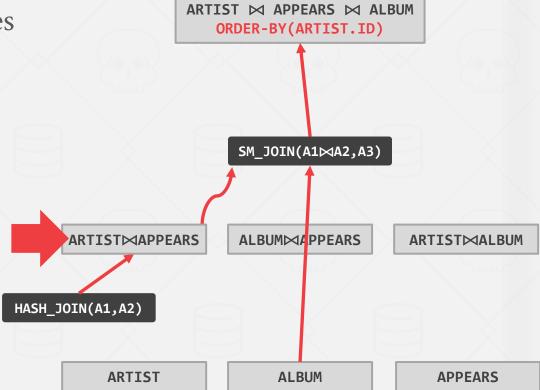

JOIN(A,B) to HASH_JOIN(A,B)

Invoke rules to create new nodes and traverse tree.

- → Logical→Logical:
 - JOIN(A,B) to JOIN(B,A)
- \rightarrow Logical \rightarrow Physical:

JOIN(A,B) to HASH_JOIN(A,B)

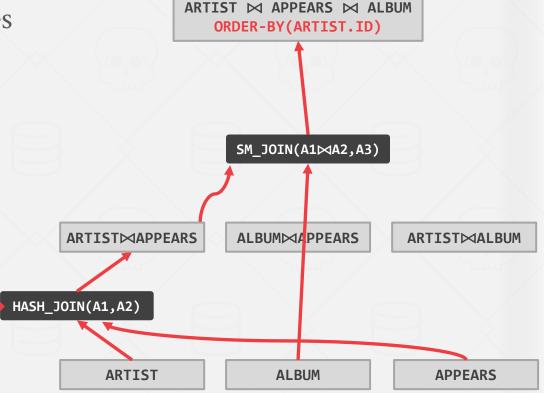

Invoke rules to create new nodes and traverse tree.

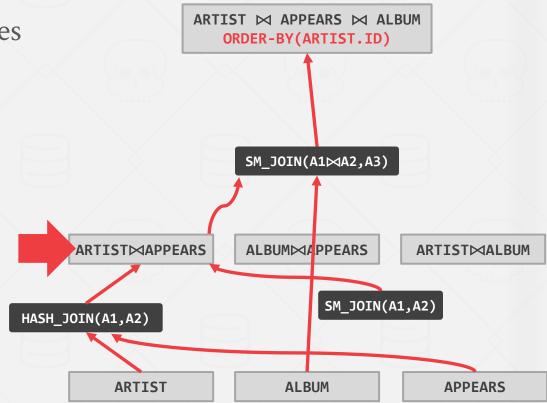

- \rightarrow Logical \rightarrow Logical:
 - JOIN(A,B) to JOIN(B,A)
- \rightarrow Logical \rightarrow Physical:

JOIN(A,B) to HASH_JOIN(A,B)

Invoke rules to create new nodes and traverse tree.

- → Logical→Logical:
- JOIN(A,B) to JOIN(B,A) \rightarrow Logical \rightarrow Physical:
- JOIN(A,B) to HASH_JOIN(A,B)

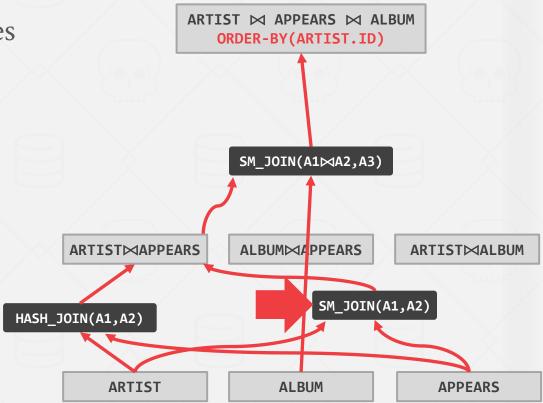

Invoke rules to create new nodes and traverse tree.

- → Logical→Logical:

 JOIN(A,B) to JOIN(B,A)
- → Logical→Physical:

 JOIN(A,B) to HASH_JOIN(A,B)

Invoke rules to create new nodes and traverse tree.

- → Logical→Logical: JOIN(A,B) to JOIN(B,A)
- → Logical→Physical:

 JOIN(A,B) to HASH_JOIN(A,B)

Invoke rules to create new nodes and traverse tree.

- → Logical→Logical:
 JOIN(A,B) to JOIN(B,A)
- → Logical→Physical:

 JOIN(A,B) to HASH_JOIN(A,B)

Invoke rules to create new nodes and traverse tree.

- → Logical→Logical:
 JOIN(A,B) to JOIN(B,A)
- → Logical→Physical:

 JOIN(A,B) to HASH_JOIN(A,B)

Invoke rules to create new nodes and traverse tree.

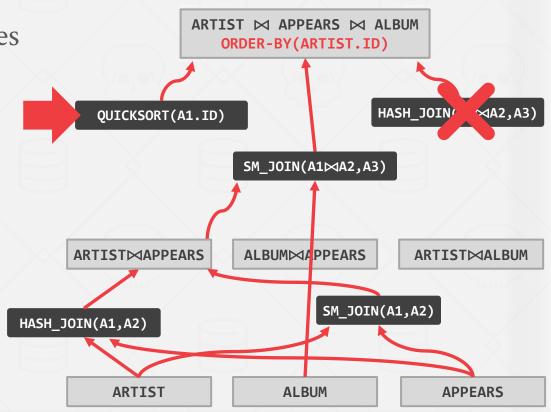

- → Logical→Logical:
 JOIN(A,B) to JOIN(B,A)
- → Logical→Physical:

 JOIN(A,B) to HASH_JOIN(A,B)

Invoke rules to create new nodes and traverse tree.

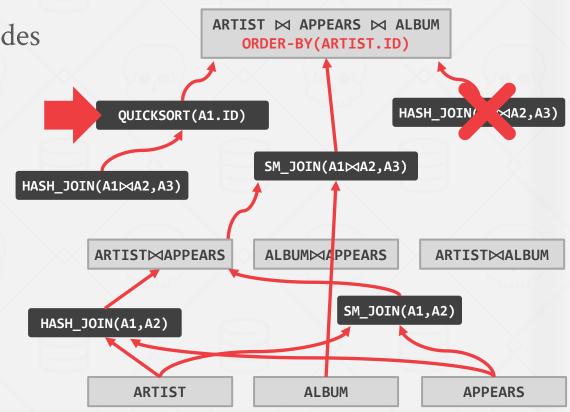

- → Logical→Logical:
 JOIN(A,B) to JOIN(B,A)
- → Logical→Physical:
 JOIN(A,B) to HASH_JOIN(A,B)

Invoke rules to create new nodes and traverse tree.

- → Logical→Logical: JOIN(A,B) to JOIN(B,A)
- → Logical→Physical:

 JOIN(A,B) to HASH_JOIN(A,B)

Invoke rules to create new nodes and traverse tree.

- → Logical→Logical: JOIN(A,B) to JOIN(B,A)
- → Logical→Physical:

 JOIN(A,B) to HASH_JOIN(A,B)

CONCLUSION

We use static rules and heuristics to optimize a query plan without needing to understand the contents of the database.

We use cost model to help perform more advanced query optimizations
